Weather API and flickr API

Description:

Once you entered the website, some information appears about your city based on your IP address (which is done by the weather API).

The information are Country Code, Time Zone, City Name, Date and Time, sunrise time, sunset time, temperature and weather description.

The weather API extracts your longitude and latitude and we send them to flickr API in order to view some photos based on these longitude and latitude

The source files are:

Index.php and bootstrap.min.css

The index.php: it has the execution code of the whole application and it is the core of the application

Bootstrap.min.css: it contains some css classes used to enhance the user interface

What is needed to run the app?

You need a sever side folder (host) to run the file using your browser

You can have your own local host by installing a program (XAMPP for example).
